**Packet transmission system.**

A packet transmission system in which variable delays are compensated for by packetizing an input signal so as to produce packets at a predetermined packet frequency (3), allocating a sequence number to each packet (6), transmitting these packets over a network to an endpoint (7), and forming the packets into an output signal at the endpoint by reference to their sequence number (12) and by delaying each as necessary (9,10) so that they are all delayed by substantially the same predetermined delay time with reference to said packet frequency. Preferably, the delay in the transmission of each packet through the network is measured by comparison of the time of arrival of the packet at the endpoint relative to a timing signal (11) synchronised with or running plesiochronously with said predetermined packet frequency. The endpoint delay is then set so that the sum of the measured delay and the endpoint delay is substantially equal to said predetermined delay time, which is assessed as the maximum delay for acceptable output signal quality.

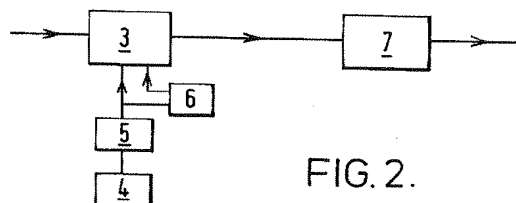

FIG. 2.

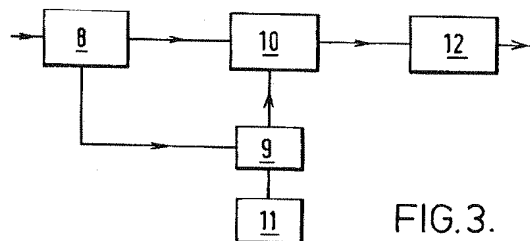

FIG. 3.

EP 0 571 189 A1

### Technical Field

This invention relates to a packet transmission system and a method of, and means for compensating for delays of packets in such a system.

It is known in a packet switching system to provide each packet with a time stamp field in which to record delays incurred as the packet traverses the system. In particular, it is known to measure the variable time taken by each packet to traverse each node of a packet switching network and to add this time to the time stamp field. Delays across the node are caused by queuing of the packets in storage means and are random in nature. The time stamp field therefore records an accumulated value of the variable delay in traversing the network, this being an especially important parameter when packets are used to transmit voiceband information, the received quality of which deteriorates unacceptably unless some form of variable delay compensation is provided. However, the use of a time stamp field in this manner increases the overhead for the packets and involves additional processing capacity at each node in the network.

### Disclosure of the Invention

An object of the present invention is to provide a packet transmission system in which variable delays can be compensated for more simply than in the known systems.

This is achieved according to the present invention by packetizing an input signal so as to produce packets at a predetermined packet frequency and allocating a sequence number to each packet, transmitting these packets over a network to an endpoint, and forming the packets into an output signal at the endpoint by reference to their sequence number and by delaying each as necessary so that they are all delayed by substantially the same predetermined delay time with reference to said packet frequency.

Preferably, the delay in the transmission of each packet through the network is measured by comparison of the time of arrival of the packet at the endpoint relative to a timing signal synchronised with or running pliesochronously with said predetermined packet frequency. The endpoint delay is then set so that the sum of the measured delay and the endpoint delay is substantially equal to said predetermined delay time, which is assessed as the maximum delay for acceptable output signal quality. Thus, variable transmission delays are accommodated within a predetermined maximum acceptable delay time which is preferably adaptively adjusted by reference to the measured delay times of successive packets so that it is reduced to a minimum.

The invention therefore avoids the need for time stamping at each node of a network, and instead by continuously producing sequenced packets at a pre-

determined frequency, the packet transmission delays can be readily measured at the endpoint with reference to this packet frequency and compensated for within said predetermined maximum acceptable delay time.

### Description of the Drawings

The invention will now be described by way of example with reference to the accompanying drawings in which:

Figure 1 is a schematic diagram of a packet transmission system,

Figure 2 is a schematic diagram of the originating endpoint of packets in the system of Figure 1,

Figure 3 is a schematic diagram of the terminating endpoint of packets in the system of Figure 1, Figure 4 is a diagram showing the timing sequence of packets within the system of Figure 1, and

Figure 5 is a diagram illustrating the distribution of measured variable delay times in the system of Figure 1.

### Mode of Carrying Out the Invention

The packet transmission system illustrated schematically in Figure 1 comprises a network of interconnected packet switching nodes 1 with endpoint devices 2 connected to them so that they can communicate with one another via the network. Data is transferred between the endpoints 2 in the form of packets within a frame format known as frame relay. Each packet has a header including a logical address field by means of which it is routed through the network. Each node refers to the logical address field in order to select the appropriate output to which to route it.

Each endpoint device 2 is capable of acting as an originating endpoint device which produces and transmits packets, or a terminating endpoint device which receives packets. Figure 2 shows an endpoint device 2 when operating as an originating endpoint. In these circumstances, a synchronous voiceband signal (e.g. digital voice, facsimile or video data) is received at a packetizer device 3 and formed into packets in a continuous manner. The packets are produced at a predetermined timing interval as determined by a clock 4 and a packetization interval generator 5. A sequence number generator 6 is driven from the interval generator 5 and allocates a sequence number to each interval, which sequence number is inserted in the header of the associated packet. A transmitter 7 receives the packets from the packetizer and transmits these to the network for delivery via the nodes 1 to a terminating endpoint device 2, such as shown in Figure 3.

At the terminating endpoint, the packets are received by a receiver 8 which reads the sequence

number from the header of each and writes this to a buffer controller 9 before passing the packet onto a buffer 10. The buffer controller 9 operates in synchronism with the packetization interval through a clock 11 synchronised with the clock 4 driving the packetization interval generator 5. The function of the buffer controller is to release packets from the buffer 10 at the correct timing so that each arrives at a de-packetizer 12 a predetermined time delay after the corresponding synchronisation signal, this time delay being sufficient to accommodate variable delays in the network.

The manner in which the buffer controller 9 operates can be better understood with reference to the timing diagram of Figure 4 which shows an example of a packet interval of 20 msec. and a predetermined delay time of 30 msec. A packet sequence number 1 arrives at the receiver 8 after suffering a delay in the network of 8 msec. The buffer controller 9 measures this delay from the arrival time of the packet and the timing signal from clock 11, and calculates that an additional delay time of 22 msec. is required to give a total delay time of 30 msec. The packet is therefore delayed in the buffer 10 for a further 22 msec. before it is released to the de-packetizer 12.

Similarly, the time of arrival of the packet sequence number 2 at the receiver 8 is monitored and the network delay time of 14 msec. calculated. This packet is then delayed in the buffer 10 for a further 16 msec. It will be noted that this second packet is passed to the de-packetizer 12 20 msec. after the first packet so that the packet interval is maintained at the terminating endpoint.

The buffer controller 9 analyses the measured delay times in the network and produces a distribution count as shown in Figure 5 which it uses to determine the optimum predetermined delay time so that it can vary this in an adaptive manner to suit the operating conditions of the system.

## Claims

1. A method of compensating for delays in a packet transmission system comprising packetizing (3) an input signal so as to produce packets at a predetermined packet frequency, allocating a sequence number (6) to each of said packets, transmitting (7) said packets in sequence over a network (1) to an endpoint (2), and processing (12) said packets to form an output signal at said endpoint by reference to the sequence numbers allocated to them, characterised by recording the time of arrival of said packets at the endpoint (2), and delaying (9) said packets at the endpoint by a variable delay so that each packet is delayed by the same predetermined time delay between transmitting (7) said packets and processing (12)

said packets at said endpoint.

2. A method as claimed in claim 1 in which the time of arrival of each packet at the endpoint is recorded (9) relative to a timing signal synchronised with or running plesiochronously with said predetermined packet frequency and used to measure the transmission delay.
3. A method as claimed in claim 2 in which the variable delay is the difference between the measured transmission delay and said predetermined time delay.
4. A method as claimed in any one of the preceding claims in which the distribution of the time of arrival of said packets at the endpoint is recorded (9) and used to adapt said predetermined time delay.
5. A method as claimed in any one of the preceding claims in which said predetermined time delay is set at a minimum acceptable value in accordance with the required quality of the output signal.
6. A packet transmission system comprising packetizing means (3) to transform an input signal into packets at a predetermined packet frequency, packet numbering means (6) to allocate a sequence member to each of said packets in sequence, transmitting means (7) to transmit said packets in sequence over a network (1) to an endpoint (2), packet processing means (12) to receive packets at said endpoint and produce a corresponding output signal by reference to the sequence numbers allocated to them, timing means (4,9) for timing the arrival of packets at the endpoint, and delaying means (9,10) for delaying said packets at the endpoint by a variable delay so that each packet is delayed by the same predetermined time delay between said transmitting means (7) and said packet processing means (12).
7. A packet transmission system as claimed in claim 6 in which the timing means comprises clock means (4) that generates a timing signal synchronised with or running plesiochronously with said predetermined packet frequency, and delay measuring means (9) which measures the transmission delay of each packet by reference to the time of arrival of the packet at the endpoint and the timing signal.
8. A packet transmission system as claimed in claim 7 in which the delaying means (9,10) determines the variable delay as the difference between the measured transmission delay and said predeter-

mined time delay.

9. A packet transmission system as claimed in any one of claims 6 to 8 including adaption means (9) which records the distribution of the time of arrival of said packets at the endpoint (Figure 5) and uses this to set said predetermined time delay. 5
  
10. A packet transmission system as claimed in claim 9 in which said adaption means (9) sets said predetermined time delay at a minimum acceptable value in accordance with the required quality of the output signal. 10
  
11. A packet transmission delay compensating system comprising packet processing means (12) to receive packets and to produce a corresponding output signal by reference to transmission sequence numbers allocated to the packets during transmission, timing means (4,9) for timing the arrival of said received packets, and delaying means (9,10) for delaying the packets by a variable delay so that each packet is delayed by the same predetermined time delay between transmission and processing by said packet processing means (12). 15  
20  
25
  
12. A packet transmission delay compensating system as claimed in claim 11 in which the timing means comprises clock means (4) that generates a timing signal synchronised with or running pleiochronously with the frequency of transmission of said packets, and delay measuring means (9) which measures the transmission delay of each packet by reference to the time of arrival of the packet and the timing signal. 30  
35
  
13. A packet transmission delay compensating system as claimed in claim 12 in which the delaying means (9) determines the variable delay as the difference between the measured transmission delay and said predetermined time delay. 40
  
14. A packet transmission delay compensating system as claimed in any one of claims 11 to 13 including adaption means (9) which records the distribution (Figure 5) of the time of arrival of said packets and uses this to set said predetermined time delay. 45  
50
  
15. A packet transmission delay compensating system as claimed in claim 14 in which said adaption means (9) sets said predetermined time delay at a minimum acceptable value in accordance with the required quality of the output signal. 55
